

Barrier definitions

For endpoint losses C_0, C_1 and path $\gamma(\lambda)$, the chord barrier is the maximum excess above the straight line joining the endpoint losses,

$$B_{\text{chord}} = \max_{\lambda} [C(\gamma(\lambda)) - ((1 - \lambda)C_0 + \lambda C_1)].$$

The worse-endpoint barrier is the maximum excess above the worse endpoint,

$$B_{\text{worse}} = \max_{\lambda} C(\gamma(\lambda)) - \max(C_0, C_1).$$

Cross-stage barrier comparison

The figure shows the best-overall test-loss barriers for $A_{\text{final}} - B_n$. It compares B_{chord} and B_{worse} , with mean $\pm$ one standard deviation over three seed pairs.

The CIFAR-10/VGG11 result is the one already shown previously. I added the same view for the Fashion-MNIST MLP. I am not sure what to conclude from this comparison yet.
